

Question 1:

(a) I believe my evaluation function (evaluationFunction) is reasonable here since the middle columns have more ways to connect 4 than the edges so it is more important to check them each game starts. Prior to the current evaluation function, I tried using 8 individual for loops to represent different evaluating situation when counting 3, counting 2, and counting 1 when evaluating horizontally from left to right (column 0-6), vertically from bottom to top(row 5-0), left-diagonally and right diagonally with ignoring 4 corners which are impossible to win, then passing `env.board[r][c]` for each for loop, with too many different for loops to iterate and too many board environment to pass, it resulted in extremely low time and space efficiency, and the minimaxAI algorithm always tended to go left instead of starting off from the most likely winning center column(optimal position). Therefore, I modified my evaluation function by changing it to always start off evaluating from the center columns to approach the optimal next moves and achieve the highest chances of winning against randomAI, stupidAI and monteCarloAI. Without using any for loops the iteration process from different ROW_COUNT and COLUMN_COUNT ranges can be deducted, and so the evaluating efficiency is significantly improved.

(b) For my evaluation function below:

```
def evaluationFunction(self, board):

    eval = 0 #counts iterate

    center= [row[3] for row in board]
#starting off at the column center

    eval+= center.count(self.position)*5
#iterate count 3 with corresponding weights
    center = [row[4] for row in board]
#for column 4 still center of column
    eval+= center.count(self.position)*3
#iterate count 2 with corresponding weights
    center = [row[2] for row in board]
#for column 2 still center of column
    eval += center.count(self.position)*3
#iterate count 1 with corresponding weights

    return eval
#return counts
```

(c) So it will not be a trivial state like the empty board. For example, it will check what would happen if adding one to every single move instead of having to evaluate what happens if one player drops in column 0, but then the second player drops from 0-6, then I would have to evaluate all of those. Instead of having to do that, here we suppose that one player drops at column 0-6 through each row while evaluating the most optimal move for the other player. Thus, from above, even though there are still certain cases minimaxAI and alphaBetaAI are unable to beat monteCarloAI, I still believe that my evaluation function is reasonable.

Question 2:

Players.py modified.
both minimax and the evaluation function implemented.

Question 3:

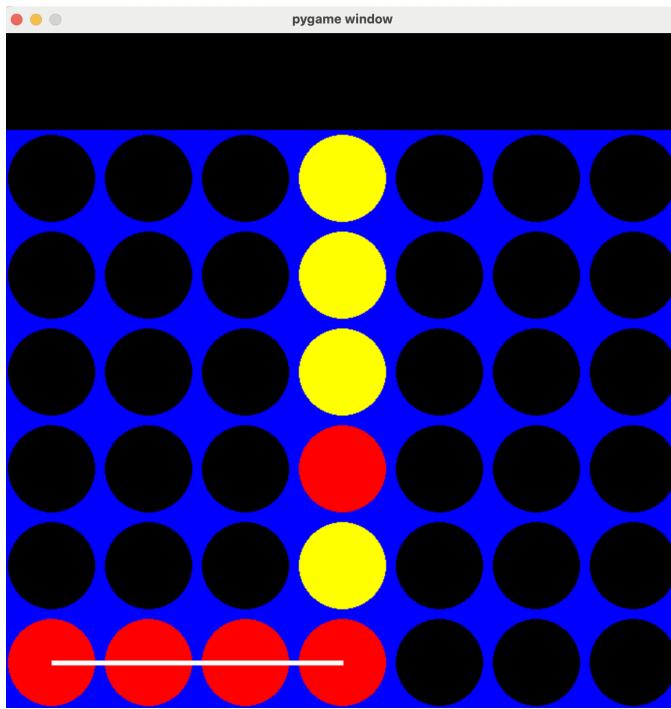

Won all 20 games against stupidAI and randomAI:

minimaxAI as Player1 VS stupidAI:

GAME 1:

Terminal command:

```
python3 main.py -p2 stupidAI -p1 minimaxAI -limit_players 1,2  
-visualize True -verbose True -seed 1
```

Terminal Result:

Player 2 has won
```

WON GAME 10 AT SEED 7 AS PLAYER 2

Successfully beat monteCarloAI for 10 times

Question 4:

Alpha-Beta pruning function implemented.

Successor function logic explanation:

```
def successor(self, state):  
    Return an array of (moves, state) pairs reachable from current state.  
    result = self.problem.successor(state)  
    self.succs += 1; self.states += len(result)  
    return result
```

We can create an array ordered 3,2,4,1,5,0,6 and call the moves like above.

Question 5:

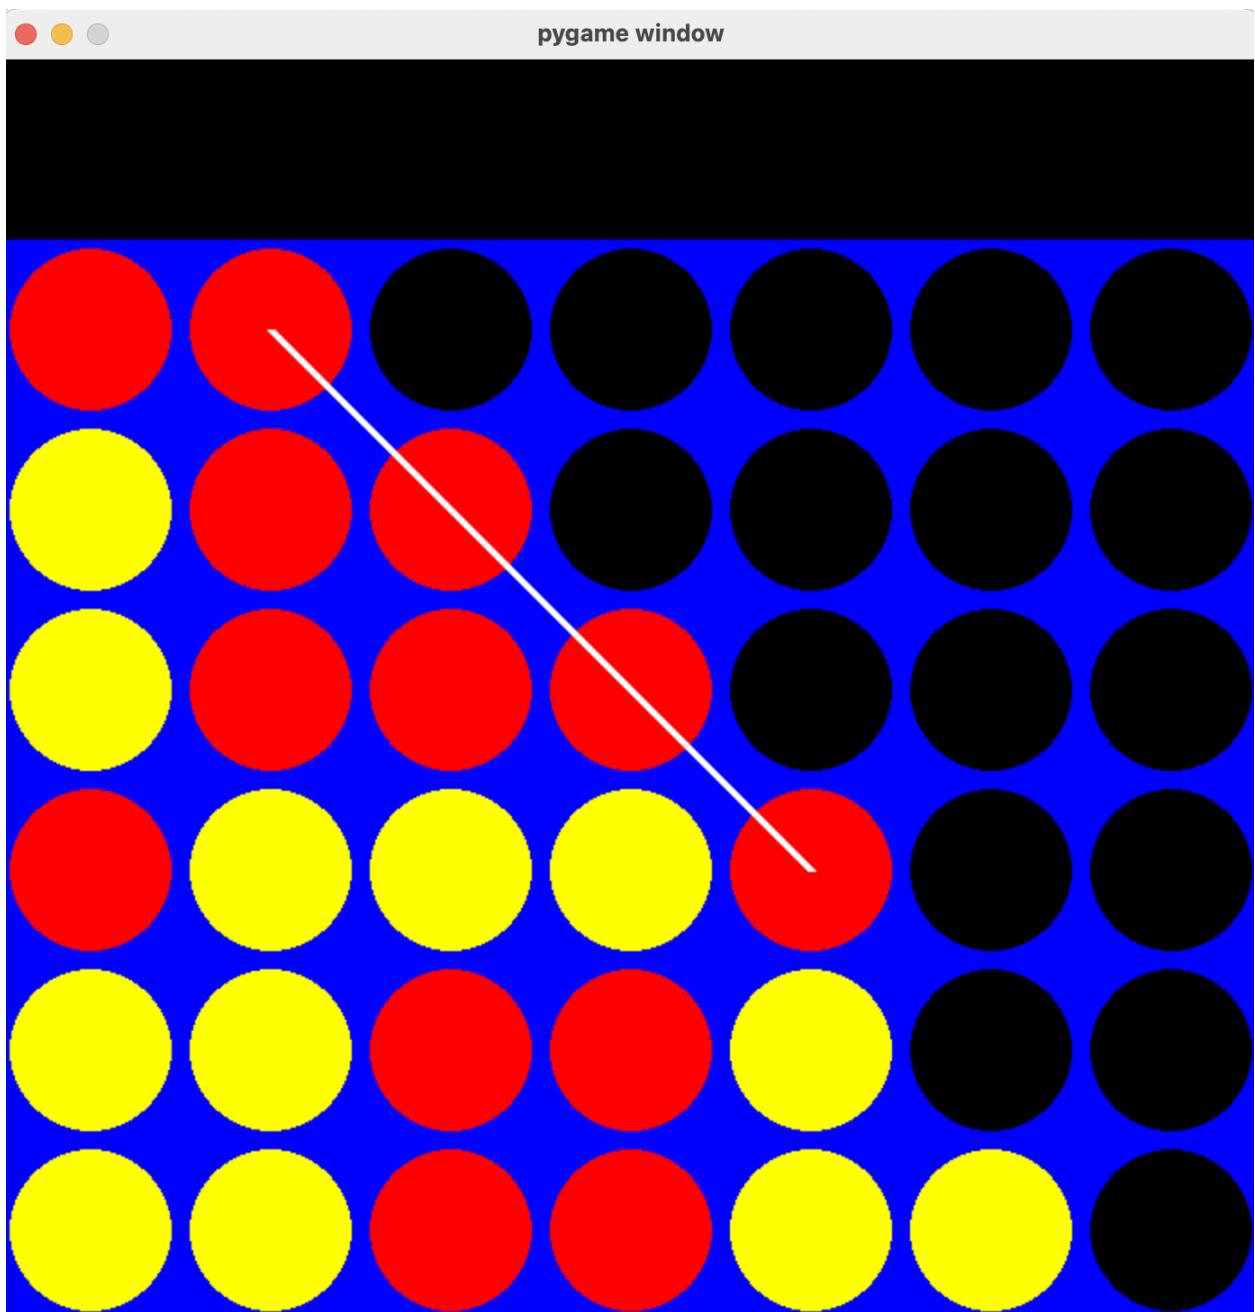

Beats monteCarlo AI all 20 times:

alphaBetaAI as Player1 VS monteCarloAI:

GAME 1:

Terminal command:

```
python3 main.py -p2 monteCarloAI -p1 alphaBetaAI -limit_players 1,2  
-visualize True -verbose True -seed 1
```

Terminal result:

```
